

Task 5

Create a template-driven form to create & update a user.

- Create a new component (UserForm).
- When you click on the create button in the users list you should navigate to the user form component.
- When you click on the update button you should also navigate to the user form component.
- Note that we will have 2 routes for the same component.
- In the user form component, you should display the input fields for the create/update operations based on the current URL.
- The user form component will have a back button and a submit button.
- When you submit the form you should display a success message in case of a successful request, then after 2 seconds of displaying the message navigate back to the previous page.
- You should handle any errors that occur and display a user-friendly message without navigating back to the previous page.
- Mark the First Name, Last Name and Email fields as required fields.
- Remember that you should disable the email field when you are updating a user.
- Disable the submit button when the form is invalid to prevent sending an Http request with invalid data.
- Use the right type of input for each form field.
